

## Partial and Semipartial Correlation Example

This SPSS output can be obtained by adding ZPP to the STATISTICS subcommand (or with menus by checking the “Part and Partial Correlations” box on the regression *Statistics* option) for the simultaneous regression of SALARY regressed on TIME and PUBS. There also is an SPSS procedure called PARTIAL CORR which will also produce partial correlations, but I find it less convenient because you can only get partial correlations for one pair of variables per command (specifying which variables to control for with the BY keyword).

```
regression vars=salary time pubs
  /descriptives=mean stdev
  /statistics=anova coeff ses r ci zpp
  /dependent=salary
  /method=enter pubs time.
```

Coefficients <sup>a</sup>

Model	Unstandardized Coefficients		Standardized Coefficients		t	Sig.	95.0% Confidence Interval for B		Correlations		
	B	Std. Error	Beta	Std. Error			Lower Bound	Upper Bound	Zero-order	Partial	Part
1 (Constant)	43082.394	3099.493			13.900	.000	36329.178	49835.610			
time years since PhD	982.867	452.057	.570	.262	2.174	.050	-2.081	1967.815	.710	.532	.430
pubs number of publications	121.801	149.699	.213	.262	.814	.432	-204.364	447.966	.588	.229	.161

<sup>a</sup>. Dependent Variable: salary annual salary in dollars

Note that “Part” refers to the semipartial correlation coefficient ( $sr$  = .161). The squared semi-partial coefficient for PUBS ( $sr^2$ ) equals the  $R$ -square change value from the hierarchical regression when PUBS is added to the model already including TIME (or the  $R$ -square change when a single variable is added):

$$sr^2 = R_{change}^2 = (.161)^2 = .026$$

Also note that the partial correlation coefficient ( $pr$ ) has no direct relationship to the  $R$ -square change value ( $pr^2 \neq R_{change}^2$ ).

The other semi-partial coefficient, .430 for TIME, bears the same relationship to  $R$ -square change. Looking at the hierarchical regression in which TIME is added to the model already including PUBS, you see that:

$$sr^2 = R_{change}^2 = (.430)^2 = .185.$$

## R code

I used the `ppcor` package to obtain the semi-partial and partial correlation coefficients. Each function outputs the correlations in the first block, the  $p$ -values in the second block, and the  $t$ -value in the third block.

#The `ppcor` package can be used to obtain the partial and semi-partial correlation coefficients

```
library(ppcor)
#semi-partial (same as R-square change)
spcor(d[,c("SALARY", "PUBS", "TIME")])
```

```
$estimate
      SALARY      PUBS      TIME
